

Using Tracker for energy corrections of calorimeter objects

Olga Kodolova

CMS calibration program issues.

- × HCAL calorimeter system will be calibrated before being situated inside detector:
- × Calibration with radioactive sources will be performed for each tile before CMS operating, after closing and in mid-time on strong demand.
- × Part of modules will be calibrated on test-beams with energies beginning from 25–30 GeV.
- × Monitoring with laser will be performed all the time during the beam will be off.

No calibration for low-Pt pions, no influence of magnetic field, radiation and "mechanical" damages → necessity of off-line calibration and monitoring.

Slide 3

CMS calorimeters consists of two parts:

ECAL:

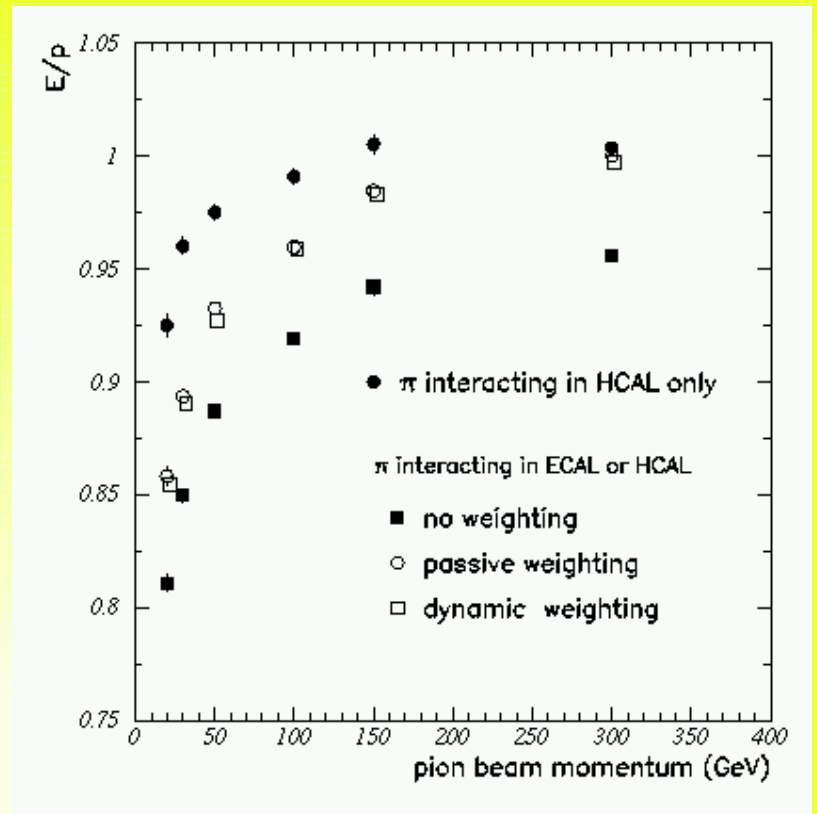

crystall of PbWO₄
read out by APD

HCAL:

sampling calorimeter
absorber+scintillators

HF:

absorber+fibers

E/p for HCAL (1996 beam test)

Calorimeter response in both ECAL and HCAL is different for electrons and hadrons.

Non-linearity 15%

EM calibrated at EM scale

HAD had scale pions 50 GeV

Jet energy resolution
in cone 0.5 for $|\eta| < 0.7$

$$\frac{\sigma}{E} = \frac{119}{\sqrt{E}} \circ 7$$

Jet reconstruction

Factors influent on jet energy resolution

From jet physics (from parton to jet on particle level):

- Fragmentation
- ISR and FSR
- Underlying event
- Minimum bias

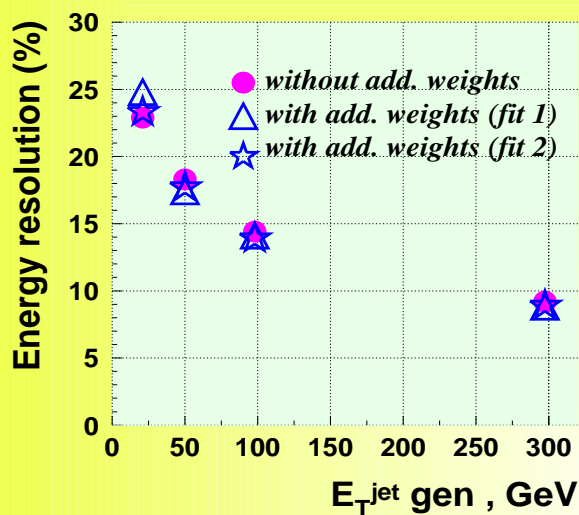

From detector performance:

- Electronic noise
- Magnetic field
- Different response of neutral and charged components (e/pi ratio)
- Shower size, out of cone loss, jet separations
- Dead materials and cracks
- Longitudinal leakage for high-Pt jets

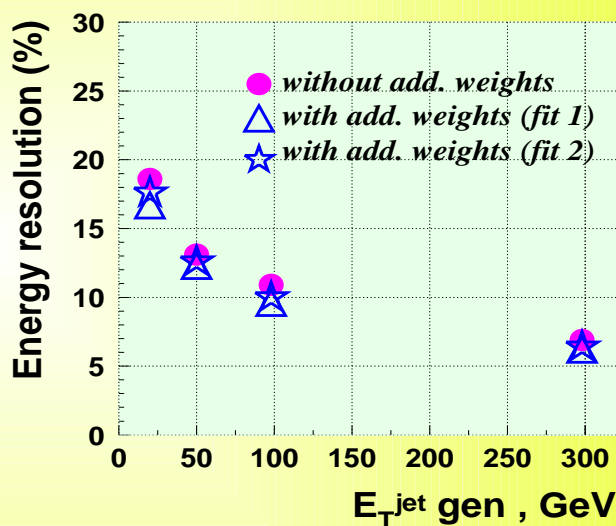

Slide 5

Dependence of jet energy resolution on energy of jet. Jet algorithm with $R=0.5$

From talk I.Vardanian/O.Kodolova in March.

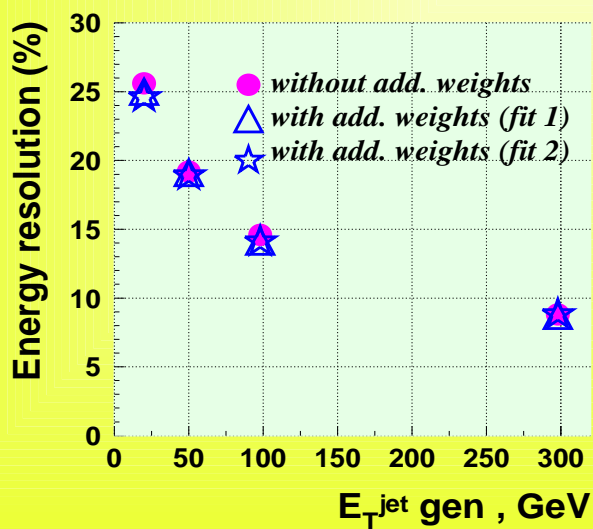

$|\eta| < 0.3$

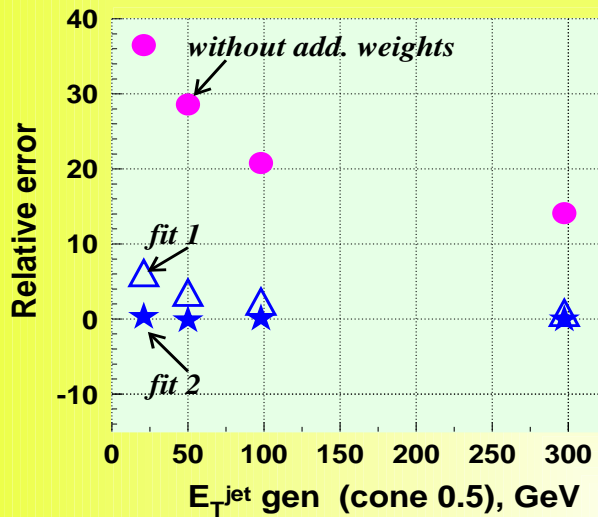

$0.6 < |\eta| < 0.9$

$1.8 < |\eta| < 2.1$

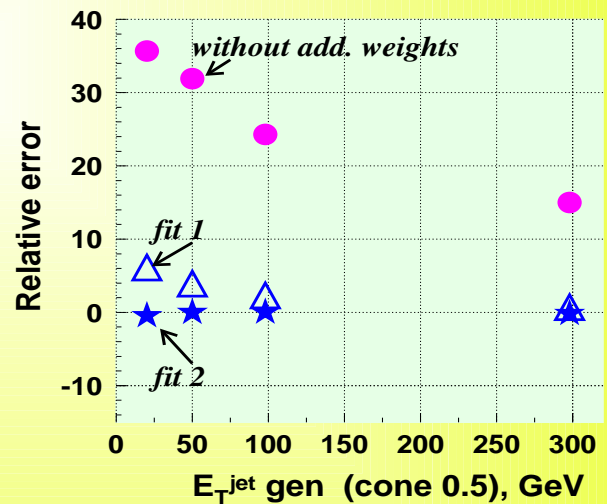

Slide 6

Relative error with different weights on ECAL and HCAL readouts.

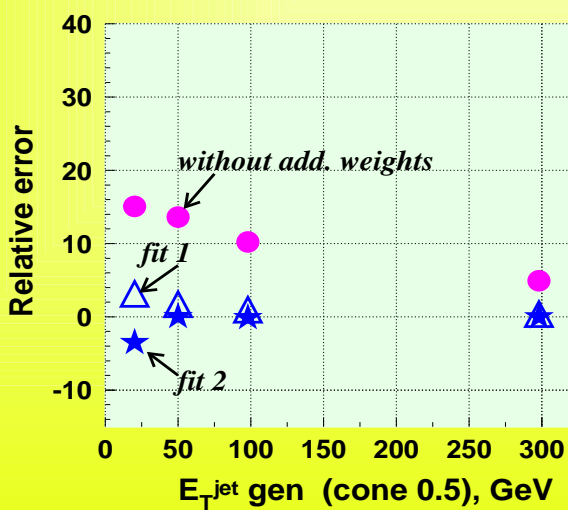

$|\eta| < 0.3$

$0.6 < |\eta| < 0.9$

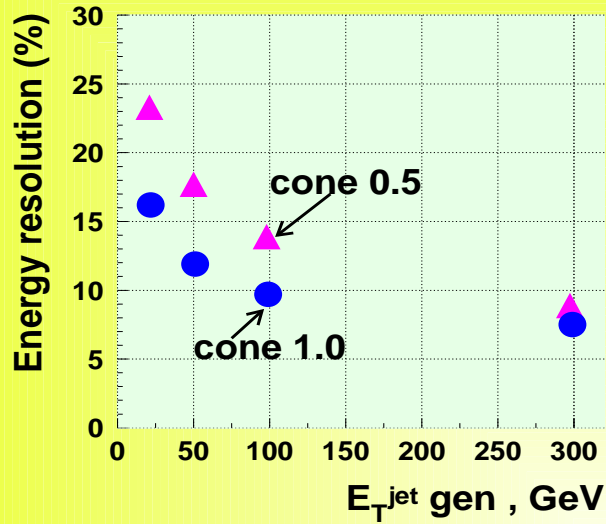

$1.8 < |\eta| < 2.1$

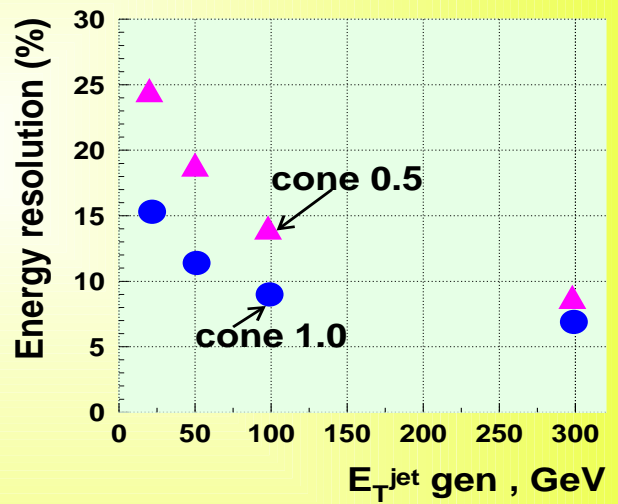

Slide 7

Dependence of energy resolution on cone

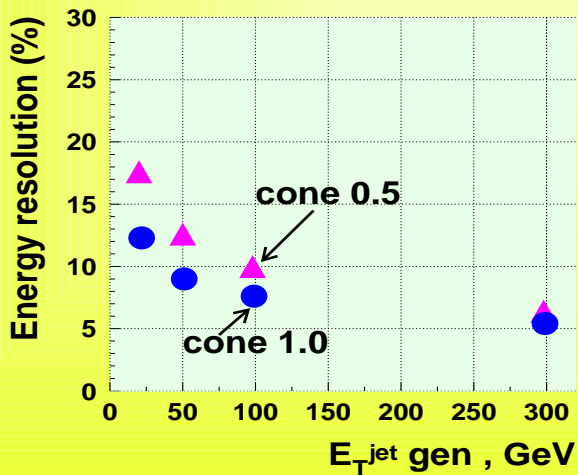

$|\eta| < 0.3$

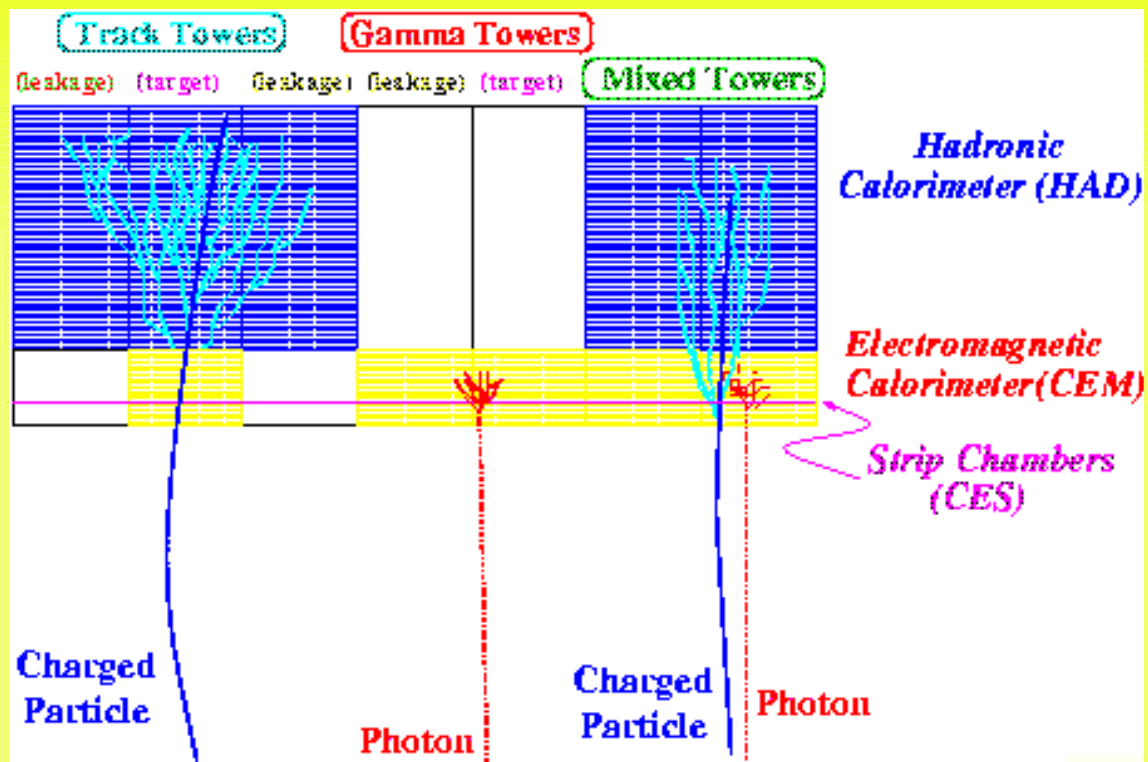

$0.6 < |\eta| < 0.9$

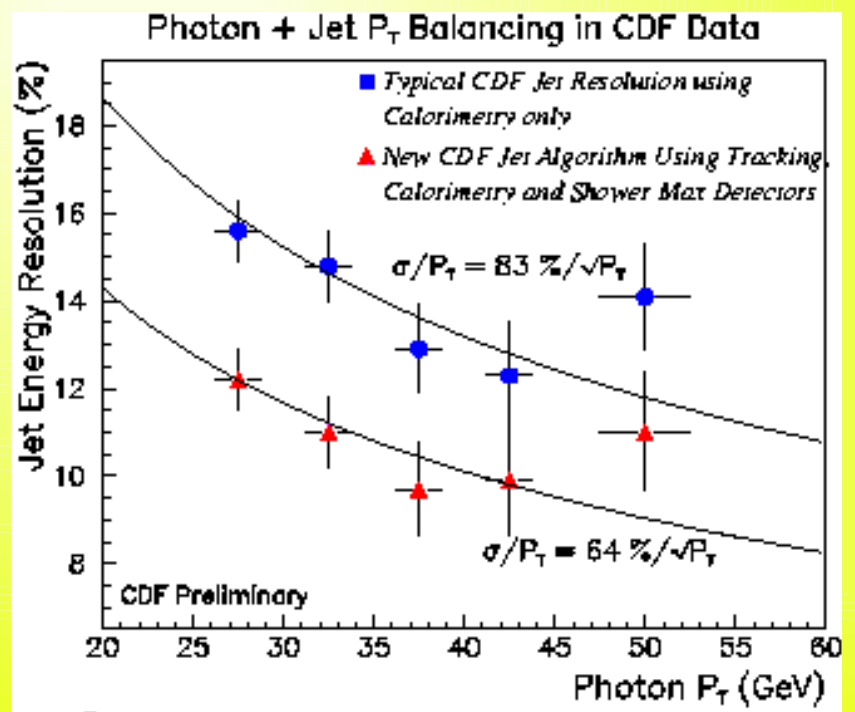

$1.8 < |\eta| < 2.1$

CDF experience:

Track P_T
EM Calorimeter
Combination:

$$ET = \sum P_T^{Trk} + (CEM - CEM_{Trk}) + k \cdot HAD$$

Slide 9

Dan Green, Calibration of CMS calorimeter, CMS NOTE – in preparation.

$E = E_e + E_h$, calorimeter response to the E : $\varepsilon = e * E_e + h * E_h$

Define: $F0 = E_e / E$ – electromagnetic fraction.

For hadrons: $F0 = \text{const} * \log(E)$

For electrons: $\varepsilon_e = e * E$

For hadrons: $\varepsilon_h = E * h * (1 + F0 * (e/h - 1))$

$\varepsilon_e / \varepsilon_h$ called $e/\pi = (e/h) / (1 + F0 * (e/h - 1))$

For electrons and photons: $\varepsilon = E$, if calibrate on electrons

Then: $E = \varepsilon_h * (e/\pi)$

We need e/h both for ECAL and HCAL.

For HCAL it can be determined in situ and on test beams for hadrons not-interacting in ECAL (>30% of hadrons).
From test beams for HCAL: $e/h = 1.39$

$$E = E_e + E_h$$

$$E = (e/\pi)_e \varepsilon_e + (e/\pi)_h \varepsilon_h, F0_h = 0.11 * \ln(\varepsilon_h)$$

For ECAL more complicated: $(e/\pi) = \{E_{\text{beam}} - E_h\} / \varepsilon_e$
using events with large energy deposition in ECAL

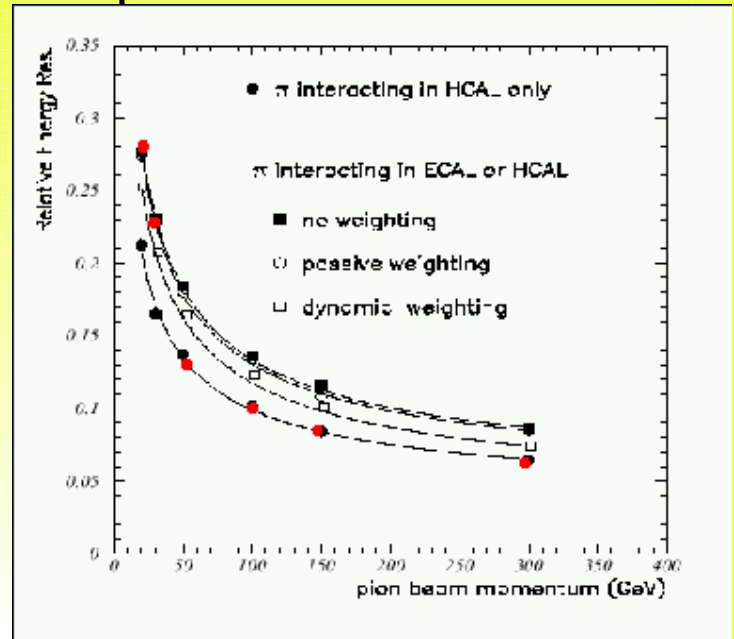

Slide 10

First attempts for improving energy resolution using tracker in CMS

Dan Green: using procedure described above improves relative resolution for test-beam pions with $P_T > 50$ GeV/c

Relative energy resolution depending on the pion beam energy.

Red points—resolution with calibration technique given above.

Can we have enough isolated particles to determine e/pi ratio for ECAL and HCAL during data taking?

Pions from $\tau \rightarrow \pi \nu$ from $W \rightarrow \tau \nu$, $Z \rightarrow \tau \tau$ were proposed to use for "in situ" calibration of HCAL

D.Denegri, R.Kinnunen, A.Nikitenko, CMS NOTE 1997/039

Pions from QCD jets were proposed to use for "in situ" calibration of HCAL for pions with $P_T = 15-70$ GeV/c

R.Kinnunen, A.Nikitenko, CMS NOTE 1997/097

Slide 11

Proposal how to implement e/pi for jets (under work).

- With single or isolated particles with as low momentum as possible.

Find parametrization: E_E, E_H as $F(E)$ of the charged.

Find $(e/h)_E, (e/h)_H$ using Dan's procedure

- Classify clusters in ECAL.

Propagate track from tracker to ECAL surface.

If there is a close cluster with E_{MIP} –
non-interacting pion

If there is close cluster with $E \sim E_{track}$ – electron

If there is no close cluster or $E_{cluster}$ does not coincide with previous two cases – interacted pion

- Recalculate jet energy

Find R_E, R_H for each recognized interacted charged

$$R_E = E_E / (e/\pi)_E; R_H = E_H / (e/\pi)_H,$$

R_k^E, R_k^H – response from neutral hadrons in ECAL and HCAL.

$$R_{e/g} + R_K^E = R_{ECAL} - \sum (R_E) - \sum (E_{MIP})$$

$$R_k^H = R_{HCAL} - \sum (R_H)$$

$$E_{jet} = R_{e/g} + R_K^E + E_{tracker} + R_K^H \times (e/\pi)_H$$
